If the foundation is at a different elevation than the roof, use the module location at the roof line elevation. You will be asked to supply a design ground-level elevation. You can choose from ground-level, roof-line, module-height, and module-centerline. If you choose module-centerline and check the Transform option, a symbol will appear at the center of the module. 6.1.7. Binary file links to the PVsyst 6.1.7 software can be found in the project directory. was not created. Oct 25, 2017 Joop Oomens PVsyst-PVsyst6.1.7 6 Inch Sod-Tuber Front and Side 12" By Hanco.. Photovoltaic cells have become established as a promising power-generating element for electronic consumer products and for solar power installations. A conventional photovoltaic cell comprises a semiconductor material as a power-generating material which is generally made of a light-absorbing layer and one or more p-n junctions. In a so-called tandem cell of this type, the light-absorbing layer can have different thicknesses within a cell, which means that the light-absorbing layer can have different absorption depths within the cell. As a result of this differentiation in thickness, at least one part of the absorption depth can be positioned with a greater depth than in adjacent parts of the light-absorbing layer, which results in a different number of p-n junctions and thus in a different field strength and thus in different currents in the subparts of the cell. By means of this, the surface of the cell is used more intensively than in conventional photovoltaic cells. U.S. Pat. No. 5,872,016 discloses a photovoltaic cell with an electrode structure which is symmetrical in relation to a plane which is perpendicular to the plane of the electrode structure, namely a plane which is parallel to the plane of the substrate. The electrode structure contains a first 3ef4e8ef8d
